

Isolation of an Eleven-Atom Polydentate Carbon-Chain Chelate Obtained by Cycloaddition of a Cyclic Osmium Carbyne with an Alkyne

Congqing Zhu, Jun Zhu, Xiaoxi Zhou, Qin Zhu, Yuhui Yang, Ting Bin Wen, and Haiping Xia*

Abstract: Carbon ligands have long played an important role in organometallic chemistry. However, previous examples of all-carbon chelating ligands are limited. Herein, we present a novel complex with an eleven-atom carbon chain as a polydentate chelating ligand. This species was formed by the [2+2+2] cycloaddition reaction of two equivalents of an alkyne with an osmapentalyne that contains the smallest carbyne bond angle (127.9°) ever observed. Density functional calculations revealed that electron-donating groups play a key role in the stabilization of this polydentate carbon-chain chelate. This process is also the first [2+2+2] cycloaddition reaction of an alkyne with a late-transition-metal carbyne complex. This study not only enriches the chemistry of polydentate carbon-chain chelates, but also deepens our understanding of the chelating ability of carbon ligands.

The metal–carbon bond is a fundamental feature of organometallic chemistry.^[1,2] Many species containing carbon ligands, such as metallocenes,^[3] metal carbonyls,^[4] metal carbenes,^[5] and metal carbynes,^[6] play a significant role in organometallic chemistry. However, examples of polydentate ligands with all-carbon chelating atoms (chelating through σ -bonds) are very rare.^[7–9] Indeed, reports of CCC-type polydentate ligands are limited, and most of these ligands contain a two-electron N-heterocyclic carbene donor.^[7b–g]

In the past few years, we have reported novel metallaromatic species, namely metallapentalynes and metallapentalenes (**I** in Scheme 1), that contain a seven-atom carbon

Scheme 1. Representative frameworks of carbolong complexes.

chain as the chelating group.^[8] Thereafter, with the extension of the chelating carbon chain, a series of organometallic frameworks were constructed (**II**, **III**, **IV**, and **VI** in Scheme 1).^[9] These species exhibit diverse properties. For instance, the planar Möbius-aromatic seven-carbon framework **I** shows aggregation-enhanced near-infrared photoluminescence,^[8a] whereas the twelve-carbon framework **VI** gives rise to a broad absorption in the near-infrared region and exhibits significant photothermal properties.^[9d] Structurally, these frameworks can be viewed as a series of long carbon chains coordinated to a transition metal. Therefore, the term “carbolong chemistry” has been used to describe the chemistry of these frameworks.^[9d] However, in the family of the carbolong complexes, the eleven-carbon framework (**V** in Scheme 1) has not been synthesized thus far.

We previously reported the synthesis of the first five-membered metal carbyne complex, osmapentalyne.^[8a,10] In this complex, the bond angle of the carbyne carbon atom (129.8°) is much smaller than that observed in the first six-membered metal carbyne, osmabenzynes (148.7°),^[10a] and both of them are far from the ideal value of 180°. The extremely small bond angle of osmapentalyne makes it highly reactive. We found that osmapentalyne reacted with nucleophiles and electrophiles to form a series of osmapentalene derivatives.^[8b,11] However, our attempts to construct the eleven-carbon framework **V** in a [2+2+2] cycloaddition reaction of two equivalents of an alkyne with the reported osmapentalynes failed.^[9b,12] In this work, we synthesized a new osmapentalyne, which has the smallest bond angle (127.9°) at the carbyne carbon reported thus far. Subsequently, the first eleven-carbon framework **V** was synthesized by a [2+2+2] cycloaddition reaction of this cyclic metal carbyne complex with two equivalents of an alkyne. The isolation of the eleven-carbon species completes the sequence of carbolong complexes.

Treatment of osmium complex **1**^[13] with an internal alkyne, dimethyl acetylenedicarboxylate (DMAD), at room temperature for 3 h afforded osmapentalyne **2a**, which was isolated as a yellow solid in 80% yield (Scheme 2). Compared to the reported osmapentalynes with high thermal stability,^[8a]

Scheme 2. Synthesis of osmapentalynes **2a** and **2b**.

complex **2a** could only be stored at room temperature for a few weeks in the solid state. Osmapentalyne **2b** was also synthesized under similar conditions.

The solid-state structure of **2a** was determined by X-ray diffraction.^[14] As shown in Figure 1, complex **2a** contains

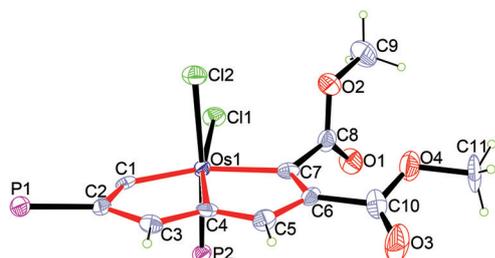

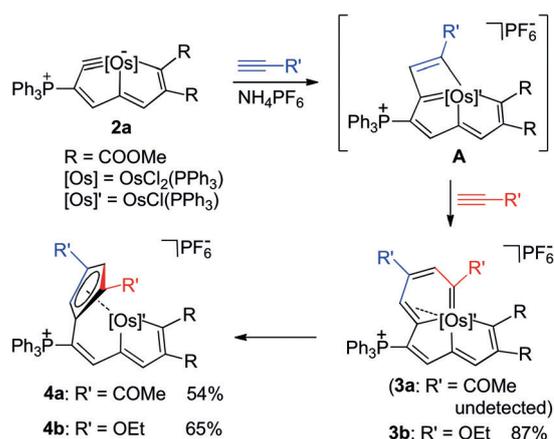

Figure 1. X-ray crystal structure of **2a**. Ellipsoids set at 50% probability. The phenyl moieties in PPh₃ are omitted for clarity.

a metal-carbon triple bond in a five-membered ring (5MR). The length of this triple bond was found to be 1.850(6) Å, which is similar to that of the first osmapentalyne (1.845(3) Å).^[8a] The C–C bond lengths (1.373–1.426 Å) in the fused 5MRs are similar to those of benzene, indicating a delocalized structure. Furthermore, **2a** features a nearly planar osmapentalyne unit, as reflected by the mean deviation (0.0407 Å) from the least-squares plane of Os1 and C1–C7 and the sums of the bond angles in the two 5MRs (539.6° and 539.9°).

Complexes **2a** and **2b** were further characterized by NMR spectroscopy and high-resolution mass spectrometry (HRMS). In the ¹³C NMR spectrum of **2a**, the resonance of the carbyne carbon atom was observed at $\delta = 325.8$ ppm, which is in the range of the signals observed for osmapentalynes ($\delta = 319.7$ – 330.8 ppm).^[8a,15] The H3 and H5 proton resonances in the fused 5MRs of **2a** appeared in the aromatic region at $\delta = 7.73$ and 9.39 ppm, respectively. In the HRMS spectrum, the molecular ion peak of **2a** was observed at 1013.1138, which is in agreement with the calculated value for $[M+Na]^+$ (1013.1112).

Notably, the carbyne bond angle (127.9(5)°) of **2a** is the smallest among the metal carbyne species studied to date.^[8a] In addition, the single phosphine and two chloride ligands on the osmium center of **2a** offer less steric protection of the Os=C bond in **2a**, which most likely leads to its higher reactivity. Therefore, we examined reactions of **2a** with alkynes to probe the possibility of [2+2+2] cycloaddition reactions towards an eleven-carbon framework **V** (Scheme 1).

In the presence of NH₄PF₆, treatment of **2a** with 3-butyn-2-one (HC≡CCHOCH₃) at room temperature for two days afforded complex **4a** in 54% isolated yield based on **2a** (Scheme 3). Complex **4a** was characterized by single-crystal X-ray diffraction (Figure 2), which clearly showed that a Cp unit is coordinated to the osmium center. The C–C bond lengths in this Cp ring range from 1.394 to 1.473 Å. Therefore, complex **4a** can be viewed as an osmacyclopentadiene and a half-osmacene connected by two sp²-hybridized carbon atoms. Notably, this is the first example of a [2+2+2]

Scheme 3. Reactions of osmapentalyne **2a** with alkynes.

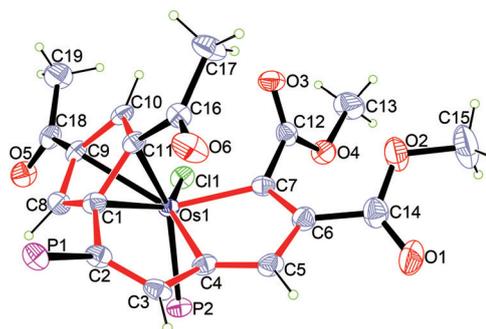

Figure 2. X-ray crystal structure of the cation of complex **4a**. Ellipsoids set at 50% probability. The phenyl moieties in PPh₃ are omitted for clarity.

cycloaddition reaction of an alkyne with a late-transition-metal carbyne complex.

We inferred that **4a** was formed by a tandem cycloaddition reaction of **2a** with two molecules of the alkyne. As shown in Scheme 3, the first alkyne molecule reacts with **2a** in a [2+2] cycloaddition reaction to give intermediate **A**, which contains a metallacyclobutadiene unit. This process is similar to the previously reported reaction of an osmapentalyne with an alkyne.^[9b] Subsequently, the second alkyne inserts into the metallacyclobutadiene unit and forms the six-membered ring (6MR) intermediate **3**, which undergoes elimination to give the final complex **4a**. A detailed mechanism for the formation of **4** is depicted in Scheme S1 in the Supporting Information.

To isolate the eleven-carbon intermediate, we studied the reaction of osmapentalyne **2a** with an electron-donating alkyne to stabilize the 6MR metallabenzene structure.^[16] In the presence of NH₄PF₆, osmapentalyne **2a** reacted with two molecules of HC≡COEt at room temperature to give complex **3b** (Scheme 3) after 5 h, which is the first example of an eleven-carbon framework isolated in the family of carbonyl complexes. Interestingly, under reflux at 60 °C for two days, complex **3b** underwent an elimination reaction to give the η^1 -cyclopentadienyl intermediate, which then rearranged to form the thermally stable η^5 -Cp complex **4b** (Scheme S1). The analogous formation of Cp complexes from metallabenzenes has previously been proposed and confirmed.^[17]

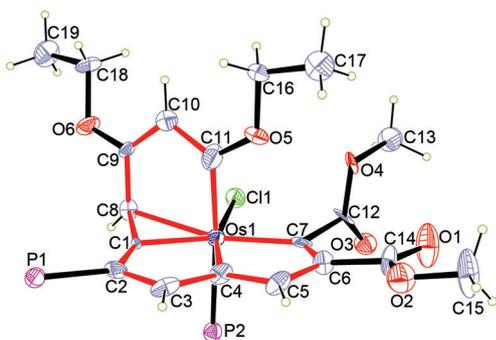

Figure 3. X-ray crystal structure of the cation of complex **3b**. Ellipsoids set at 50% probability. The phenyl moieties in PPh_3 are omitted for clarity.

The solid-state structure of **3b** was determined by single-crystal X-ray diffraction, and one of the two independent molecules with similar structures in the unit cell is shown in Figure 3. Unexpectedly, the 6MR in complex **3b** is extremely distorted, and the dihedral angle between the Os1/C8/C9/C10/C11 and the Os1/C1/C8 plane is 102.7° . However, the two 5MRs are nearly coplanar, as reflected by the small mean deviation from the least-squares plane (0.0380 \AA). The Os1-C8 bond ($2.253(6) \text{ \AA}$) is clearly longer than the Os1-C1 ($1.949(6) \text{ \AA}$) and Os1-C11 ($2.023(7) \text{ \AA}$) bonds. The nearly equal Os-C bond lengths (Os1-C1 $1.949(6) \text{ \AA}$, Os1-C4 $2.049(7) \text{ \AA}$, Os1-C7 $2.030(6) \text{ \AA}$) and the C-C bond lengths ($1.391\text{--}1.420 \text{ \AA}$) in the fused 5MRs indicate the delocalized nature of this osmapentalene unit in complex **3b**.

Structurally, complex **3b** can be viewed as an eleven-atom carbon chain coordinated to the osmium center. The 6MR in **3b** is not coplanar with the osmapentalene unit, in contrast to the planar structures observed for other members of the carbolong family. Density functional theory (DFT) calculations showed that this non-coplanar structure of **3b** is more stable than the corresponding planar one (Scheme S2 and

Figure 4). Therefore, the framework of **3b** also represents the first non-planar structure in the carbolong family.

The NMR spectroscopic data of complex **3b** are consistent with its X-ray structure. In particular, in its ^1H NMR spectrum, the resonances of H3 and H5 were observed at shifts of $\delta = 9.35$ and 8.84 ppm, respectively, which are similar to those of the proton resonances for the osmapentalenes.^[8b,18] In the ^{13}C NMR spectrum, the resonances for C1 and C11 were observed at $\delta = 241.6$ and 236.2 ppm, respectively. In addition, the molecular ion peak in the HRMS spectrum of **3b** was observed at 1095.2381 , which is in agreement with the calculated value (1095.2386). The solid-state structure of **4b** was also corroborated by NMR spectroscopy and HRMS. The NMR data of **4b** are similar to those of **4a** (see the Supporting Information).

In the reactions of complex **2a** with alkynes, the electron-donating group on the alkyne plays a crucial role in the stabilization of the 6MR in **3b**. To gain more insight into the substituent effect in these reactions, we performed DFT calculations on simplified models with PH_3 groups in place of the PPh_3 groups. Figure 4 shows the energy profile calculated for the conversion of the planar 6MR intermediate **G'** into the final complex **4'** (a full energy profile for this reaction is shown in Figure S1). Interestingly, the non-planar structure **3'** is more stable than the planar structure **G'**, irrespective of whether the substituent on the ring is electron-withdrawing (**3a'**) or electron-donating (**3b'**). The calculated Os1-C8 bond length in **3b'** (2.249 \AA) is close to that (2.253 \AA) determined from its X-ray structure, which is obviously shorter than that in **3a'** (2.586 \AA) and indicates a stronger interaction between the Os1 and C8 atoms in **3b'**. Moreover, the energy barrier for the conversion of **3b'** into **4b'** was calculated to be $24.5 \text{ kcal mol}^{-1}$, which is higher than that for the formation of **4a'** from **3a'** ($14.5 \text{ kcal mol}^{-1}$). These values indicate that electron-donating groups increase the energy barrier for the conversion of **3'** into **4'**, which is consistent with the experimental observation that only **3b** was isolated and converted into **4b** at reflux.

In conclusion, we have described the synthesis of a new osmapentalene with the smallest carbyne bond angle ever reported. Thereafter, the first eleven-atom carbon chain chelating to a transition metal was obtained by the first $[2+2+2]$ cycloaddition of a late-transition-metal carbyne complex with an alkyne. DFT calculations showed that the electron-donating group on the alkyne plays a crucial role in the stabilization of the 6MR intermediate. The non-planar eleven-carbon framework is an important member in the carbolong family because it expands our understanding of the chelating ability of carbon ligands. In addition, a $[2+2]$ cycloaddition reaction between metal carbyne and alkyne has been proposed as a key step in alkyne metathesis. Therefore, this study provides a new perspective for the application of late-transition-metal carbyne species as catalysts in alkyne metathesis or alkyne polymerization reactions.

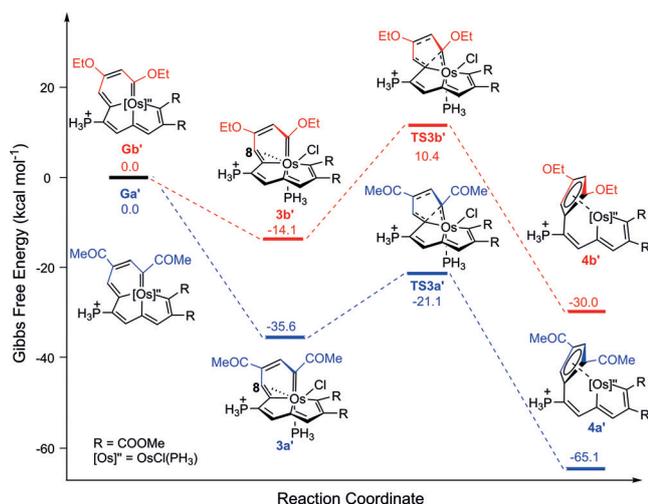

Figure 4. Energy profile (kcal mol^{-1}) for the conversion of the planar 6MR intermediate **G'** into Cp complex **4'**. The pathways for derivatives with electron-donating and electron-withdrawing groups in the 6MR are shown in red and blue, respectively.
